The problem discussed is the stability of two input-output feedforward and feedback relations, under an integral-type constraint defining an admissible class of feedback controllers. Sufficiency-type conditions are given for the positive, bounded and of closed range feed-forward operator to be strictly positive and then boundedly invertible, with its existing inverse being also a strictly positive operator. The general formalism is first established and the linked to properties of some typical contractive and pseudocontractive mappings while some real-world applications and links of the above formalism to asymptotic hyperstability of dynamic systems are discussed later on.

1. Introduction

The properties of absolute stability and hyperstability and asymptotic hyperstability of dynamic systems are very important tools in dynamic systems since they are associated with the positivity and boundedness of the energy for all feedback controllers within a wide class characterized by a Popov-type integral inequality, then implying global Lyapunov's stability [1–8]. The fact that such properties hold for a class of controllers defined by the Popov inequality, rather than for just some individual one, makes the related theory to be very useful against potential parametrical dispersion of components. The main objective of this paper is the investigation of the strict positivity and stability of bounded positive one-to-one operators with closed range on Hilbert spaces linked to contractive, pseudocontractive, asymptotically pseudocontractive, and asymptotically pseudocontractive in the intermediate sense mappings. See [9–21] and exhaustive list of references therein. Fixed point theory has also been proven to be useful to describe the asymptotic behaviour, stability and equilibrium points of differential, functional, and difference equations and systems of equations, and continuous-time, discrete-time, and hybrid dynamic systems. See, for instance, [22–27] and references therein. Further links with technical results and some real-world examples are established through the paper related to the relevant problems of absolute stability and asymptotic hyperstability of continuous-time and discrete-time dynamic systems [1–8]. Such dynamic systems possess the significant physical property that their associate input-output energy is non-negative and finite for all time. Thus, they are purely dissipative systems, for a wide class of feedback nonlinear time-varying controllers satisfying an integral input-output inequality what leads to the global Lyapunov's stability for all controllers within such a class. Several operators are characterized but the most important one in the analysis is the one which maps the input space to the output space. Both such spaces are subspaces of a Hilbert space resulting to be, typically in real-world examples, either the space of square-integrable real or complex functions (or, in general, vector functions) or its corresponding square-summable counterparts. The relevant property needed for a positive operator to be strictly positive is seen to be that its minimum modulus be nonzero so as to ensure that it is invertible if it is of a closed range. Note, on the other hand,
that the crucial property for the boundedness and stability of the operator restricted to the Hilbert space of interest is that it will be stable on its whole definition domain.

2. Problem Statement and Main Results

Through this paper, one considers the complex Hilbert space $H$ on $C$ and operators $G : H \to H$ and $K : H \to H$ which define the following associated relations:

$$
y = Gu + y_t,

u = Kr - q_r(y),
$$

where $y_t = y_t(p)$ and $p \in C^d$ is some given complex parameterizing vector, and $r : \Gamma \to H$ is such that $\Gamma = \Gamma_0$, the nonnegative integer set for picking up values $t \in \Gamma$ of the continuous-time argument and $\Gamma$ discrete-time argument) where $\Gamma = \Gamma_0$, the nonnegative integer set for picking up values $t \in \Gamma$ of the discrete-time argument) where $\Gamma$ is assumed to be bounded and of closed range is.

The general formalism is given in Section 2 together with some links to contractive and pseudocontractive mappings while some real-world applications to asymptotic hyperstability of dynamic systems are then given in Section 3. The following preliminary result holds.

**Proposition 1.** Assume that $G : H \to H$ is a one-to-one linear operator with closed range. Then, the following properties hold

(i) $G : H \to H$ is invertible with nonzero minimum modulus,

(ii) if, in addition, $G : H \to H$ is positive (abbreviated notation being $G \geq 0$), then $\langle Gu, u \rangle > 0$ for any nonzero $u : \Gamma \to H$,

(iii) there is $t \in \Gamma$ such that $\langle GP_tu, P_tu \rangle > 0$ for any nonzero $u \in \text{dom}(G)$.

**Proof.** Since $G$ on $H$ is one-to-one with closed range, it is also invertible from the open mapping theorem and then bounded below, so that there is $c \in R$, such that

$$
\|Gu\| = \langle Gu, Gu \rangle^{1/2} \geq c\|u\| = c\langle u, u \rangle^{1/2}; \text{ } \forall u \in \text{dom}G.
$$

(2)

Then, the minimum modulus $\mu(G)$ of $G$ satisfies

$$
\mu(G) = \inf \left\{ \frac{\|Gu\|}{\|u\|} : u \in \text{dom}G \neq 0 \right\} \geq c > 0
$$

(3)

and Property (i) has been proven. Now, if $G \geq 0$, then there is a self-adjoint operator $\bar{G} = G^* \geq 0$ on $X$ such that $G = \bar{G}$ so that, since $\mu(\bar{G}) > 0$ from Property (i),

$$
\langle Gu, u \rangle^{1/2} = \langle \bar{G}u, u \rangle^{1/2} = \langle \bar{G}, \bar{G}u \rangle^{1/2}
$$

$$
= \|\bar{G}u\| = \|\bar{G}u\|^{1/2} \|u\|

\geq \inf \left\{ \frac{\|\bar{G}u\|}{\|u\|} : u \in \text{dom}G \neq 0 \right\} \|u\|

\geq \mu(\bar{G}) \|u\| > 0; \text{ } \forall u \neq 0 : \Gamma \to H
$$

(4)

and Property (ii) is proven.

(iii) Note that if $u \neq 0$, then there is $t \in \Gamma$ such that $P_tu \neq 0$ and $\langle GP_tu, P_tu \rangle > 0$ since one gets by Property (ii) that

$$
\langle Gu, u \rangle^{1/2} = \sup_{t \in \Gamma} \langle GP_tu, P_tu \rangle^{1/2} \geq \langle GP_tu, P_tu \rangle^{1/2}
$$

$$
= \langle \bar{G}^{1/2}P_tu, P_tu \rangle^{1/2} = \|\bar{G}(P_tu)\| = \|\bar{G}(P_tu)\|^{1/2} \|P_tu\|

\geq \inf \left\{ \frac{\|\bar{G}(P_tu)\|}{\|P_tu\|} : u \in \text{dom}G \neq 0 \right\} \|P_tu\|

\geq \mu(\bar{G}) \|P_tu\| > 0; \text{ } \forall u \neq 0 : \Gamma \to H.
$$

(5)
Proposition 3. \( G : H \to H \) is a one-to-one linear bounded operator with closed range if and only if it is invertible with nonzero minimum modulus.

Definition 2. The operator \( G : H \to H \) is said to be strictly positive (denoted as \( G > 0 \)) if it is positive (i.e., \( G \geq 0 \)) and \( \mu(G) > 0 \).

Note from Proposition 1 that if \( G \geq 0 \) is a one-to-one operator on \( H \) with closed range, then it is invertible and \( G > 0 \).

It is also direct to prove that Property (i) of Proposition 1 is equivalent to its given assumption so that one has [28].

Proposition 3. \( G : H \to H \) is a one-to-one linear bounded operator with closed range if and only if it is invertible with nonzero minimum modulus.

Definition 2 that

\[ \mu(G) > 0 \quad \text{and} \quad \mu(G) < \infty \] (iii) follows.

\[ \mu(G) > 0 \]

Thus, \( \langle GPu, Pu \rangle > 0 \) for some \( t \in \Gamma \) if \( u \neq 0 \). Hence, Property (iii) follows.

Thus, \( \langle GPu, Pu \rangle > 0 \) for some \( t \in \Gamma \) if \( u \neq 0 \). Hence, Property (iii) follows.

\[ \mu(G) > 0 \]

Thus, \( \langle GPu, Pu \rangle > 0 \) for some \( t \in \Gamma \) if \( u \neq 0 \). Hence, Property (iii) follows.

Thus, \( \langle GPu, Pu \rangle > 0 \) for some \( t \in \Gamma \) if \( u \neq 0 \). Hence, Property (iii) follows.

\[ \mu(G) > 0 \]

Thus, \( \langle GPu, Pu \rangle > 0 \) for some \( t \in \Gamma \) if \( u \neq 0 \). Hence, Property (iii) follows.

Thus, \( \langle GPu, Pu \rangle > 0 \) for some \( t \in \Gamma \) if \( u \neq 0 \). Hence, Property (iii) follows.

\[ \mu(G) > 0 \]

Thus, \( \langle GPu, Pu \rangle > 0 \) for some \( t \in \Gamma \) if \( u \neq 0 \). Hence, Property (iii) follows.

Thus, \( \langle GPu, Pu \rangle > 0 \) for some \( t \in \Gamma \) if \( u \neq 0 \). Hence, Property (iii) follows.

\[ \mu(G) > 0 \]

Thus, \( \langle GPu, Pu \rangle > 0 \) for some \( t \in \Gamma \) if \( u \neq 0 \). Hence, Property (iii) follows.

Thus, \( \langle GPu, Pu \rangle > 0 \) for some \( t \in \Gamma \) if \( u \neq 0 \). Hence, Property (iii) follows.

\[ \mu(G) > 0 \]

Thus, \( \langle GPu, Pu \rangle > 0 \) for some \( t \in \Gamma \) if \( u \neq 0 \). Hence, Property (iii) follows.

Thus, \( \langle GPu, Pu \rangle > 0 \) for some \( t \in \Gamma \) if \( u \neq 0 \). Hence, Property (iii) follows.

\[ \mu(G) > 0 \]
where \(0 < \gamma = \sup_{t \in \Gamma} \gamma_t < \infty\). Now, since \(K\) is a bounded operator, \(r\) is a bounded function, \(P_t y_t \to 0\) as \(t \to \infty\), and \(G > 0\) is bounded and one-to-one with closed range so that \(G > 0\) is also bounded and one-to-one with closed range implying from Proposition 1 that \(\mu(G) = \mu^2(\bar{G}) > 0\), and one gets from (12) that

\[
\liminf_{\Gamma^* \to \infty} \left[ \gamma_t + \langle P_t (GP_t u), P_t (Kr) \rangle \gamma_t - \mu^2(\bar{G}) \|P_t u\|^2 \right] 
\geq \liminf_{\Gamma^* \to \infty} \left[ \gamma_t + \langle P_t (GP_t u), P_t (Kr) \rangle \right] 
\geq - \mu^2(\bar{G}) \|P_t u\|^2 
\geq 0.
\]

Assume that there is some unbounded \(u : \Gamma \to H\). Then, the subsequent contradiction

\[
0 \leq \liminf_{\Gamma^* \to \infty} \left[ \gamma_t + \mu^2(\bar{G}) (\lambda - \|P_t u\|) \|P_t u\| \right] = -\infty
\]

follows from (13) for some \(\lambda \in \mathbb{R}_{\geq 0}\) since \(\mu(\bar{G}) > 0\). Then any \(u : \Gamma \to H\) is bounded. Since the operator \(G\) on \(H_e\) is bounded, it is stable, and then \(G : H_e \to H\) is also bounded and causal, and, since the function \(u : \Gamma \to H\) is bounded, then \(y_j : \Gamma \to H\) is also bounded with \(\|y_j\| \leq \|G\|\|u\|\) and \(\|P_t y_j\| \leq \|P_t G P_t u\| \leq \|G\|\|u\| \forall t \in \Gamma\), and \(y : \Gamma \to H\) is also bounded since \(y = y_h + y_j\). On the other hand, if \(r : \Gamma \to H\) is identically zero, then one gets from (13)

\[
0 \leq \mu(\bar{G}) \liminf_{\Gamma^* \to \infty} \|P_t u\| \leq \gamma < \infty, \text{ and, since } \mu(\bar{G}) > 0, \text{ then } \exists \liminf_{\Gamma^* \to \infty} u(t) = 0.
\]

Also, it is clear that, since \(u : \Gamma \to H_e\), and since \(u : \Gamma \to H\) is bounded and converges asymptotically to zero and \(\|y_j\| \leq \|G\|\|u\|\), then \(u : \Gamma \to H\), \(y_j : \Gamma \to H_e\), and then \(\exists \liminf_{\Gamma^* \to \infty} y(t) = \liminf_{\Gamma^* \to \infty} y_j(t) = 0 \text{ since } y_h : \Gamma \to H\) is bounded and asymptotically vanishing.

The assumption 6 of Theorem 5 can be relaxed leading to the following stronger result.

**Corollary 6.** Theorem 5 holds if its assumption 6 is relaxed to

\[
\liminf_{t \to \infty} \langle P_t y, P_t (\hat{q}_t(y)) \rangle \geq -\gamma > -\infty.
\]

**Proof.** Note that (7) still holds since it is independent of assumption 6. The constraint (12) is modified as follows:

\[
\liminf_{\Gamma^* \to \infty} \langle P_t y, P_t (Kr) \rangle + \gamma_t - \mu^2(\bar{G}) \|P_t u\|^2 
- \langle P_t (y_h), P_t (Kr - \hat{q}_t(y)) \rangle \geq 0
\]

which makes (13) to remain valid, and Theorem 5 still holds.

In a physical context, \(E = \langle y, u \rangle\) is the whole input-output energy of (1), \(E(t) = \langle P_t y, P_t u \rangle\) is the input-output energy dissipated on \([0, t] \cap \Gamma\), and \((u + y)(t)\) is the instantaneous input-output power at \(t \in \Gamma\) while \((Gu + y_h, Kr)\) is the energy supplied by the external source. Particular cases of interest in control engineering are (a) if the reference input \(r \equiv 0\), then the feedback control system is a regulator evolving only from its initial conditions, (b) if such reference is a constant real level, then the control system is a position servomechanism, (c) if the reference \(r(t) = Kt\) for \(t \in \Gamma\), then the control system is a velocity servomechanism and so forth.

On the other hand, the extended Popov-type control inequality of the controller \((P_t y, P_t (\hat{q}_t(y))) \geq -\gamma > -\infty\) and \(G > 0\) implies that \(0 \leq E(t) \leq \gamma < \infty\) for any nonzero control input with compact support; \(\forall t \in \Gamma\) and all \(\hat{q}_t(y)\) satisfying the assumption 6 of Theorem 5; that is, the input-output energy is nonnegative and bounded; \(\forall t \in \Gamma\). The use of such a constraint allows the simultaneous investigation of the maintenance of the positivity and stability properties of (1) under a class of nonlinear time-varying controllers (defined by such a Popov constraint itself) rather than for a particular controller device belonging to such a class.

Note that \(G\) on \(H_e\) is stable since \(\|Gu\| \leq M\|u\|\) for some finite \(M \in \mathbb{R}_{\geq 0}\); \(\forall t \in \Gamma\) and, equivalently, \(G : H_e \to H\) is bounded. Now, one concludes from Proposition 4 for the system defined by the inverse operator \(G^{-1}\) that \(0 \leq \langle P_t (G^{-1} u), P_t u \rangle < \infty\) for any admissible control input \(u\) since \(G^{-1} > 0\), bounded and causal.

The following result basically reformulates Theorem 5 if \(G \mid H\) is a strictly positive pseudocontraction. Since the contribution of initial conditions and a bounded exogenous reference do not modify the stability properties, as seen from Theorem 5, they are assumed to be null in the sequel.

**Theorem 7.** Assume that the relationships of (1) hold for all \(t \in \Gamma\) with \(r \equiv 0\), \(y_0 = 0\), \(G : H_e \to H_e, \hat{q}_t : \Gamma \times H_e \to \text{ ran } \hat{q}_t\), and, furthermore,

\[
(1) G : H_e \to H \text{ is bounded and causal, one-to-one, and with closed range.}
\]

\[
(2) G > 0.
\]

\[
(3) \langle P_t y, P_t (\hat{q}_t(y)) \rangle \geq -\gamma > -\infty; \forall t \in \Gamma.
\]

Then, \(u, y, y : \Gamma \to H\) are bounded, and \(u(t) \to 0\), \(y(t) \to 0\) as \((\Gamma \ni t) \to \infty\). Furthermore, one gets for any, \(u_1, u_2 : \Gamma \to \text{ ran } \hat{q}_t\) that

\[
\langle u_1 + u_2, u_1 \rangle + \langle u_1, u_2 \rangle \leq \frac{2 \gamma}{\mu^2(\bar{G})}.
\]

If, in addition, \(G \mid H\) is a pseudocontraction, then

\[
0 \leq \langle Gu - Gu_2, u_1 - u_2 \rangle \leq \gamma \min \left(1, \frac{4}{\mu^2(\bar{G})} \right)
\]

with the lower-bound equating zero if and only if \(u_1 = u_2\).

**Proof.** Take the relation proved in Theorem 5 \(\langle y, u \rangle = \langle Gu + y_h, Kr - \hat{q}_t(y) \rangle\) under zero exogenous reference and initial conditions in (1) to yield

\[
0 < \mu^2(\bar{G}) \langle u, u \rangle \leq \langle Gu, u \rangle = \langle \bar{G}u, u \rangle \leq \gamma < \infty.
\]
Since $G > 0$ then $G = G^*$, and one gets for $u = u_1 - u_2$
\[
0 \leq \langle Gu_1 - Gu_2, u_1 - u_2 \rangle = \langle \tilde{G}u_1 - \tilde{G}u_2, \tilde{G}u_1 - \tilde{G}u_2 \rangle
\]
\[
= \langle Gu_1, u_1 \rangle + \langle Gu_2, u_2 \rangle - \langle Gu_1, u_2 \rangle - \langle Gu_2, u_1 \rangle
\]
\[
\leq 2\gamma - \langle Gu_1, u_2 \rangle - (u_2, Gu_1)
\]
\[
= 2\gamma - \langle Gu_1, u_2 \rangle - \langle Gu_1, u_2 \rangle^*
\Rightarrow
\]
\[
0 \leq \max \left(0, \langle Gu_1, u_2 \rangle + \langle Gu_1, u_2 \rangle^* \right)
\]
\[
\leq \langle Gu_1 - Gu_2, u_1 - u_2 \rangle - \langle Gu_1, u_2 \rangle^* \leq 2\gamma < \infty
\]
\[
0 \leq \|u_1 - u_2\|^2 = \langle u_1 - u_2, u_1 - u_2 \rangle
\]
\[
= \|u_1\|^2 + \|u_2\|^2 - \langle u_1, u_2 \rangle - \langle u_1, u_2 \rangle^* \leq \frac{2\gamma}{\mu^2(G)} - \langle u_1, u_2 \rangle - \langle u_1, u_2 \rangle^*
\]
\[
(19)
\]
and $\langle u_1, u_2 \rangle + \langle u_1, u_2 \rangle^* \leq 2\gamma/\mu^2(G)$. Assume that $G > 0$ is, furthermore, a pseudocontraction on $H$. Then,
\[
0 \leq \langle Gu_1 - Gu_2, u_1 - u_2 \rangle
\]
\[
= \langle \tilde{G}u_1 - \tilde{G}u_2, \tilde{G}u_1 - \tilde{G}u_2 \rangle \leq \|u_1 - u_2\|^2
\]
and, equivalently,
\[
\|Gu_1 - Gu_2\|^2 \leq \|u_1 - u_2\|^2 + \|I - G\|u_1 - (I - G) u_2\|^2
\]
\[
0 \leq \langle Gu_1 - Gu_2, u_1 - u_2 \rangle \leq \langle Gu_1 - \tilde{G}u_2, \tilde{G}u_1 - \tilde{G}u_2 \rangle
\]
\[
\leq \|u_1 - u_2\|^2 \leq \frac{2\gamma}{\mu^2(G)} - \langle u_1, u_2 \rangle - \langle u_1, u_2 \rangle^*
\]
\[
(21)
\]
implies that
\[
\langle u_1, u_2 \rangle + \langle u_1, u_2 \rangle^* < \langle Gu_1 - Gu_2, u_1 - u_2 \rangle
\]
\[
+ \langle u_1, u_2 \rangle^* \leq \frac{2\gamma}{\mu^2(G)},
\]
\[
(22)
\]
and the following cases can occur.

(a) $0 \leq \langle Gu_1 - Gu_2, u_1 - u_2 \rangle \leq \min \left(\gamma, 2\gamma/\mu^2(G) - \langle u_1, u_2 \rangle - \langle u_1, u_2 \rangle^* \right)$ if the controls $u_1$ and $u_2$ fulfill $0 < \langle u_1, u_2 \rangle + \langle u_1, u_2 \rangle^* < 2\gamma/\mu^2(G)$.

(b) $0 \leq \langle Gu_1 - Gu_2, u_1 - u_2 \rangle \leq \min \left(\gamma, 2\gamma/\mu^2(G) - \|u_1, u_2\|^2 \right)$ if the controls $u_1$ and $u_2$ fulfill $\langle u_1, u_2 \rangle + \langle u_1, u_2 \rangle^* < 0$.

\[
(c) 0 < 2\gamma/\mu^2(G) \leq \langle Gu_1 - Gu_2, u_1 - u_2 \rangle \leq \gamma
\]
if the controls $u_1$ and $u_2$ fulfill $\langle u_1, u_2 \rangle + \langle u_1, u_2 \rangle^* \geq 2\gamma/\mu^2(G)$. This case is only feasible with equality.

Combining the cases one gets that
\[
0 \leq \langle Gu_1 - Gu_2, u_1 - u_2 \rangle \leq \gamma \min \left(1, \frac{4}{\mu^2(G)} \right)
\]
(23)

with the lower-bound equating zero if and only if $u_1 = u_2$; that is $u = u_1 - u_2 = 0$.

Basically, Theorem 7 states that a strictly positive operator, which is also a pseudocontraction, subject to a feedback control law satisfying a Popov-type inequality, keeps the boundedness of the input-output energy with a modified upper-bound which improves that associated to the Popov inequality if the minimum modulus of $G$ satisfies $\mu(G) > 4$. The following result guarantees the fulfilment of Theorem 5 if $G : H \rightarrow H$ is strictly positive and asymptotically pseudocontractive in the intermediate sense under a modified Popov-type inequality.

**Theorem 8.** Assume that

1. $G > 0$ is one-to-one, bounded, causal, and of closed range with minimum modulus $\mu(G) > \alpha$,
2. $G : H \rightarrow H$ is asymptotically pseudocontractive in the intermediate sense satisfying the constraint,
\[
0 \leq \langle P_1 \tilde{y}, P_1 \tilde{P}_2 P_1 - P_1 \tilde{P}_2 \rangle \leq \alpha \|P_1 \tilde{u}_1 - P_1 \tilde{P}_2 \|^2;
\]
\[
\forall \tau \in \Gamma
\]
(24)

for some real convergent sequence $\{\alpha_t\}_{t \in \Gamma}$ in $[\alpha, \infty)$ such that $\alpha_t \rightarrow \alpha \in (0,1]$ as $T(\in \Gamma) \rightarrow \infty$ and zero initial conditions and exogenous reference in (1), where
\[
\tilde{y}_t = y_{t+T} - y_t = P_1 + T y - P_1 y,
\]
\[
\tilde{u}_t = u_{t+T} - u_t = P_1 + T u - P_1 u
\]
(25)

are incremental values of $y$ and $u$ with $t, t + T \in \Gamma$ being adjacent elements in the strict ordering on $\Gamma$ if such an indexing set is discrete and $[t, t + T]$ being a closed interval of nonzero constant Lebesgue measure $T$ in $\Gamma$ if such an indexing set is real.

(3) the following inequality holds:
\[
\lim \inf_{T \rightarrow \infty} \left( \langle P_1, y_1, P_1 (q_1(\tilde{y})) \rangle + \alpha \|\tilde{u}_1\|^2 \right) \geq 0.
\]
(26)

Then, $u, y : \Gamma \rightarrow H$, and they are bounded, and, furthermore, $u(t) \rightarrow 0$, $y(t) \rightarrow 0$ as $T(\in \Gamma) \rightarrow \infty$ under a zero exogenous input and initial conditions.

**Proof.** Since $G : H \rightarrow H$ is asymptotically pseudocontractive in the intermediate sense
\[
0 \leq \langle P_1 \tilde{y}, P_1 \tilde{P}_2 P_1 \tilde{u}_1 - P_1 \tilde{u}_2 \rangle
\]
\[
= \langle P_1 GP_1 \tilde{u}_1 - P_1 GP_1 \tilde{u}_2, P_1 \tilde{u}_1 - P_1 \tilde{u}_2 \rangle
\]
\[
\leq \alpha \|P_1 \tilde{u}_1 - P_1 \tilde{u}_2 \|^2;
\]
\[
\forall \tau \in \Gamma
\]
(27)
Theorem 10. Assume that obtain the subsequent result.

of any bounded exogenous reference under bounded initial boundedness-type stability properties related to the injection by

since

\[ \lim_{t \to \infty} (\alpha \pi^2) = 0, \]

then one has

\[ 0 \leq \mu^2 (G) \pi^2 \leq \sum_{n=1}^{\infty} (\alpha_n \pi^2) \leq 0, \]

so that, if \( \alpha = \lim_{t \to \infty} \alpha_t < \mu^2 (G), \)

lim sup \( \frac{\mu^2 (G) \pi^2}{\alpha_n \pi^2} \leq 0 \) and \( u(t) \to 0 \) as \( t \to \infty. \)

Thus, \( u \colon \Gamma \to H \) is bounded since it is piecewise continuous with eventual bounded discontinuities, and \( T > 0 \) and finite. Since \( G \) on \( H_x \) and \( G \) restricted to \( H \) are stable, \( y \colon \Gamma \to H \) is also bounded and converges to zero. \( \square \)

A particular case of Theorem 8 of interest is as follows.

Corollary 9. Theorem 8 holds if the assumption 2 is replaced by \( G \colon H \to H \) being a pseudocontraction.

Proof. It follows since Theorem 8 holds, in particular, under the condition \( \alpha_t = \alpha = 1; \forall t \in \Gamma. \) \( \square \)

If \( G : H \to H \) is strictly positive and contractive, we obtain the subsequent result.

Theorem 10. Assume that

(1) \( G \) is one-to-one, bounded, causal, and of closed range.

(2) \( G : H \to H \) satisfies the following positive-bounded and contractive constraints for some given \( \beta \in \Gamma \) and \( u = u_1 \sim u_2; \)

\[ 0 \leq \left\langle P_0 G \rho u_1 - P_0 G \rho u_2, P_0 u_1 - P_0 u_2 \right\rangle \leq \mu^2 (G) \pi^2 \leq \sum_{n=1}^{\infty} (\alpha_n \pi^2) \leq 0, \]

and

\[ 0 \leq \left\langle P_0 G \rho u_1 - P_0 G \rho u_2, P_0 u_1 - P_0 u_2 \right\rangle \leq \mu^2 (G) \pi^2 \leq \sum_{n=1}^{\infty} (\alpha_n \pi^2) \leq 0, \]

Thus, \( u(t) = u_1(t) \sim u_2(t) \to 0 \) as \( t \to \infty. \) Since \( u \equiv 0 \) is an admissible control, one concludes that any admissible control is bounded and it converges asymptotically to zero. The output \( y(t) \) has a similar property. \( \square \)

3. Application Examples

Example 1. Define the truncated function within the time interval \([0, t]; \forall t \in R_0^+\) of \( f : R \to R \) as follows:

\[ f_t (\tau) = f(t) \]

\[ 0 \]

\[ \begin{cases} f(t) & \text{for } \tau \in [0, t] \\ 0 & \text{otherwise.} \end{cases} \]

Thus, the output of a single-input single-output linear time-invariant continuous-time dynamic system of nth order and initial state \( x(0) = x_0 \in R^n \) under a piecewise continuous control with eventual isolated bounded discontinuities \( u : R \to R \cap H, \) where \( H = L^2(R_0^+); L^2(0, \infty) \) the Hilbert space of the square-integrable functions on \( R_0^+ \), is

\[ y(t) = \int_0^t g(t, \tau) u(\tau) d\tau + c(t, x_0) \]

\[ = \int_{-\infty}^0 g(t, \tau) u_1(\tau) d\tau + c(t, x_0) \]

\[ = (g \ast u)(t) + c(t, x_0), \quad \forall t \in R_0^+ \]
where \( \Gamma = \mathbb{R}_0^+ = \{ z \in \mathbb{R} : z \geq 0 \} \), \( g : \mathbb{R} \times \mathbb{R} \to \mathbb{R} \) is the impulse response, \( c(t, x_0) \) is the zero-input response (i.e., the response contribution due to initial conditions) for initial state \( x_0 \), and \( \ast \) stands for the convolution integral operator. Since the dynamic system is realizable, \( g(t, \tau) = 0 \) for \( \tau > t \). The complex function \( G : \mathbb{C} \to \mathbb{C} \) defined as \( G(s) = L(g(t)) \) is the transfer function, where \( L \) stands for the Laplace transform of the impulse response where it exists. After defining \( y(t) = 0 \) for \( t < 0 \), the input-output energy obeys the following relations by using twice Parseval's theorem:

\[
E(t) = \int_0^t y(\tau)u(\tau) d\tau = \int_0^\infty y(\tau)u_i(\tau) d\tau
\]

\[
= \frac{1}{2\pi} \int_{-\infty}^{\infty} Y(\omega)U_i(-\omega) d\omega = \langle y, u \rangle_1 = \langle y, u_i \rangle
\]

\[
= \frac{1}{2\pi} \int_{-\infty}^{\infty} G(\omega)U_i(\omega)U_i(-\omega) d\omega
\]

\[
+ \int_0^t c(\tau, x_0) u(\tau) d\tau
\]

\[
= \frac{1}{2\pi} \int_{-\infty}^{\infty} G(\omega)[U_i(\omega)]^2 d\omega
\]

\[
+ \int_0^t c(\tau, x_0) u(\tau) d\tau
\]

\[
= \frac{1}{2\pi} \langle GU_i, U_i \rangle + \int_0^t c(\tau, x_0) u(\tau) d\tau
\]

\[
\geq \frac{1}{2\pi} \left( \min_{\omega \in \mathbb{R}_0^+} \text{Re} G(\omega) \right) \int_{-\infty}^{\infty} |U_i(\omega)|^2 d\omega
\]

\[
= \left( \min_{\omega \in \mathbb{R}_0^+} \text{Re} G(\omega) \right) \int_0^t |u(\tau)|^2 d\tau
\]

\[
+ \int_0^t c(\tau, x_0) u(\tau) d\tau
\]

\[
= \left( \min_{\omega \in \mathbb{R}_0^+} \text{Re} G(\omega) \right) \langle u_i, u_i \rangle + \int_0^t c(\tau, x_0) u(\tau) d\tau
\]

\[
= \left( \min_{\omega \in \mathbb{R}_0^+} \text{Re} G(\omega) \right) \langle u_i, u_i \rangle + \int_0^t c(\tau, x_0) u(\tau) d\tau
\]

\[
\leq \gamma(t, x_0) + \int_0^t y(\tau) k(\tau) r(\tau) d\tau.
\]

Note that any hodograph \( G(\omega) \) has the symmetry rules \( \text{Re} G(\omega) = \text{Re} G(-\omega) \) and \( \text{Im} G(\omega) = -\text{Im} G(-\omega) \). Also, \( \mu(G) \geq \min_{\omega \in \mathbb{R}_0^+} \text{Re} G(\omega) > 0 \). Thus, one gets by combining (37) and (40)

\[
\left( \min_{\omega \in \mathbb{R}_0^+} \text{Re} G(\omega) \right) \int_0^t |u(\tau)|^2 d\tau + \int_0^t c(\tau, x_0) u(\tau) d\tau
\]

\[
\leq \gamma(t, x_0) + \int_0^t y(\tau) k(\tau) r(\tau) d\tau; \quad \forall t \in \mathbb{R}_0^+.
\]

Decompose \([0, t] = I_{2\varepsilon}(t) \cup I_{1\varepsilon}(t)\) for each \( t \in \mathbb{R}_0^+ \), where

\[
I_{1\varepsilon}(t) = \{ \tau \in [0, t] : |u(\tau)| \leq \varepsilon \},
\]

\[
I_{2\varepsilon}(t) = \{ \tau \in [0, t] : |u(\tau)| > \varepsilon \}.
\]
for some given prefixed $\varepsilon \in \mathbb{R}_+$. Note that one (but not both) of the disjoint sets $I_{i}(t)$ for $i = 1, 2$ can be empty. Then, by direct calculations one gets the following:

\[
\min_{\omega \in \mathbb{R}_+} \text{Re} G(\omega) \left( \int_0^t |u(\tau)|^2 d\tau + \int_0^t c(\tau, x_0) u(\tau) d\tau \right) \\
\quad \geq \left( \min_{\omega \in \mathbb{R}_+} \text{Re} G(\omega) \right) \int_0^t |u(\tau)|^2 d\tau - \epsilon \int_{I_{1}(t)} |c(\tau, x_0)| \, d\tau \\
\quad + \int_{I_{2}(t)} \frac{c(\tau, x_0)}{u(\tau)} |u(\tau)|^2 \, d\tau
\]

\[
\geq \left( \min_{\omega \in \mathbb{R}_+} \text{Re} G(\omega) \right) \int_0^t |u(\tau)|^2 d\tau - \epsilon \int_{I_{1}(t)} |c(\tau, x_0)| \, d\tau \\
\quad - \int_{I_{2}(t)} \left| \frac{c(\tau, x_0)}{u(\tau)} \right| |u(\tau)|^2 \, d\tau
\]

\[
\geq \left( \min_{\omega \in \mathbb{R}_+} \text{Re} G(\omega) \right) \int_0^t |u(\tau)|^2 d\tau - \epsilon \int_{I_{1}(t)} |c(\tau, x_0)| \, d\tau
\]

Assume that $\sup_{t \in \mathbb{R}_+} |k(t)| \leq \overline{k}$ and $\sup_{t \in \mathbb{R}_+} |r(t)| \leq \overline{r}$. Then, one gets from (41) and (43) that

\[
\int_0^t \left( |u(\tau)| - \overline{k} \max_{\omega \in \mathbb{R}_+} |G(i\omega)| \right) |u(\tau)| \, d\tau \\
\leq \frac{1}{\min_{\omega \in \mathbb{R}_+} \text{Re} G(i\omega) - \overline{r}^{-1} \max_{\omega \in \mathbb{R}_+} |c(t, x_0)|} \times \left( y(t, x_0) + \epsilon \int_{I_{1}(t)} |c(\tau, x_0)| \, d\tau \right),
\]

\forall t \in \mathbb{R}_+.

This relation leads to the following result.

**Proposition 11.** Assume that

1. $k, r \in L_{\infty}(\mathbb{R}_+)$ so that $\sup_{t \in \mathbb{R}_+} |k(t)| \leq \overline{k} < \infty$ and $\sup_{t \in \mathbb{R}_+} |r(t)| \leq \overline{r} < \infty$,

2. the transfer function $G(s)$ is strictly strictly positive real; that is, $\text{Re} G(s) > 0$ for all complex $s$ with $\text{Re} s \geq 0$,

3. $\lim_{t \to \infty} y(t, x_0) = 0$ and $\lim_{t \to \infty} y(t, x_0) = 0$,

Then, one gets the following properties for any given initial state $x_0 \in \mathbb{R}^n$.

(i) $u, y \in L_{\infty}(\mathbb{R}_+)$.

(ii) $\lim_{t \to \infty} \int_0^t y(t) k(t) r(t) \, d\tau > -\infty$; $\lim_{t \to \infty} \left( u(t) - y(t) k(t) r(t) \right) \to 0$.

(iii) If $|u(t)|^2 \geq y(t) k(t) r(t)$; $\forall t \in \mathbb{R}_+$, then $\lim_{t \to \infty} \left( |u(t)|^2 - y(t) k(t) r(t) \right) = 0$. If, in addition, $k(t) = k$ and $r(t) = r$ are nonzero constants; $\forall t \in \mathbb{R}_+$, then

\[
\lim_{t \to \infty} y(t) = y_{\infty} \quad \text{and} \quad \lim_{t \to \infty} u(t) = u_{\infty} = k r \int_0^\infty g(r) \, dr \quad \text{and} \quad \lim_{t \to \infty} y(t) = y_{\infty} = k r \int_0^\infty g(r) \, dr.
\]

(iv) if $r = 0$, then $u(t) \to 0$ and $y(t) \to 0$ as $t \to \infty$ and are both square-integrable on $\mathbb{R}_+$; $\forall x_0 \in \mathbb{R}^n$.

Thus, the closed-loop dynamic system (36), (38) is asymptotically hyperstable (i.e., globally asymptotically Lyapunov's stable, [1–3]) since the state of any minimal state-space realization is also square-integrable on $\mathbb{R}_+$, and it converges asymptotically to zero as time tends to infinity for any controller device $\varphi : [0, t] \times \mathbb{R} \to \mathbb{R}$ satisfying (39).

**Proof.** Since the transfer function $G(s)$ is strictly positive real then it is strictly stable (i.e. all its poles are in Res $\leq -\rho < 0$ for some $\rho \in \mathbb{R}_+$) and $\text{Re} G(s) > 0$ for all complex $s$ with Res $\geq 0$. Since it is, furthermore, strongly positive real (i.e., a strictly positive operator on $L^2(\mathbb{R}_+)$), and it is associated to a dynamic system, so that it is realizable, then it is rational with pole-zero excess is zero (otherwise, if the pole-zero excess was $+1$, then it could not be strongly strictly positive real since $\lim_{s \to \infty} \text{Re} G(is) = 0$, and if the pole-zero excess was $-1$, then it would not be realizable.) Since it has the same number of zeros and poles, and it is strongly strictly positive real, then its modulus is everywhere bounded in its definition domain, invertible, and of bounded inverse, so that one has

\[
0 < \min_{\omega \in \mathbb{R}_+} \text{Re} G(i\omega) \leq \max_{\omega \in \mathbb{R}_+} |G(i\omega)| < +\infty.
\]

Note that $\int_{I_{1}(t)} |c(t, x_0)| \, d\tau \leq \int_0^\infty |c(r, x_0)| \, d\tau = y(x_0) < +\infty$ since $\lim_{t \to \infty} y(t, x_0) = 0$ at exponential rate since the dynamic system is strictly stable. Since $\epsilon \in \mathbb{R}_+$ can be chosen arbitrarily to build the disjoint union $I_{1}(t) \cup I_{2}(t)$ equalizing $[0, t]$; $\forall t \in \mathbb{R}_+$, then choose $\epsilon > |c(t, x_0)|/(\min_{\omega \in \mathbb{R}_+} \text{Re} G(is))$. Now, assume that $u : \mathbb{R} \to \mathbb{R}$ is unbound. Since, it is piecewise continuous with eventual bounded discontinuities, then $\lim_{t \to \infty} \int_0^t |u(\tau)| \, d\tau = +\infty$ which implies that $\int_0^t (|u(\tau)| - \overline{k} \max_{\omega \in \mathbb{R}_+} |G(i\omega)|) |u(\tau)| \, d\tau$ is strictly increasing so that the subsequent contradiction follows

\[
+\infty = \lim_{t \to \infty} \int_0^t \left( |u(\tau)| - \overline{k} \max_{\omega \in \mathbb{R}_+} |G(i\omega)| \right) |u(\tau)| \, d\tau \\
\leq \lim_{t \to \infty} \int_0^t \left( |u(\tau)|^2 - k(t) r(t) v(t) \right) \, d\tau \\
\leq \frac{1}{\min_{\omega \in \mathbb{R}_+} \text{Re} G(i\omega) - \overline{r}^{-1} \max_{\omega \in \mathbb{R}_+} |c(t, x_0)|} \times \left( y(t, x_0) + \epsilon \int_{I_{1}(t)} |c(\tau, x_0)| \, d\tau \right) < +\infty,
\]

$\forall t \in \mathbb{R}_+$.

Thus, $u \in L_{\infty}(\mathbb{R}_+)$. Since $G(s)$ is strictly stable and $u \in L_{\infty}(\mathbb{R}_+)$, then $y \in L_{\infty}(\mathbb{R}_+)$. Property (i) has
been proved. On the other hand, if \( \liminf_{t \to \infty} (|u(t)|^2 - y(t)k(t)r(t)) > 0 \), then \( \lim_{t \to \infty} \int_0^t (|u(\tau)|^2 - k(\tau)r(\tau)y(\tau)) \, d\tau = +\infty \), and the above contradiction holds. Then, \( \liminf_{t \to \infty} \int_0^t (|u(\tau)|^2 - y(t)k(t)r(t)) \leq 0 \). Note also that if \( \lim_{t \to \infty} \int_0^t y(r)k(r)r(\tau) \, d\tau = -\infty \), then the subsequent contradiction follows

\[
0 \leq \lim_{t \to \infty} \int_0^t |u(\tau)|^2 \, d\tau \\
\leq \frac{1}{\min_{\tau \in \mathbb{R}_+} \text{Re} \, G(ik) - e^{-\epsilon} \max_{\tau \in \mathbb{R}_+} |c(t, x_0)|} \\
\times \left( y(t, x_0) + \int_0^t [c(\tau, x_0) + k(\tau) r(\tau) y(\tau)] \, d\tau \right) \\
= -\infty, \quad \forall t \in \mathbb{R}_+.
\]

(47)

Then, \( \liminf_{t \to \infty} \int_0^t y(r)k(r)r(\tau) \, d\tau > -\infty \). Property (ii) has been proven.

Note that \( \exists \lim_{t \to \infty} (|u(t)|^2 - y(t)k(t)r(t)) = 0 \) if \( |u(t)|^2 \geq y(t)k(t)r(t); \forall t \in \mathbb{R}_+ \) is a direct consequence of \( \liminf_{t \to \infty} (|u(\tau)|^2 - y(t)k(t)r(t)) \leq 0 \) from Property (ii). This proves the first part of Property (iii). Also, if \( k(t) = k \) and \( r(t) = r \) are nonzero constants; \( \forall t \in \mathbb{R}_+ \), then \( \lim_{t \to \infty} (|u(t)|^2 - y(t)kr) = 0 \).

Now, if \( r(t) \) is identically zero in \( \mathbb{R}_+ \), then

\[
\lim_{t \to \infty} \int_0^t |u(\tau)|^2 \, d\tau \\
\leq \frac{1}{\min_{\tau \in \mathbb{R}_+} \text{Re} \, G(ik) - e^{-\epsilon} \max_{\tau \in \mathbb{R}_+} |c(t, x_0)|} \\
\times \left( y(t, x_0) + \epsilon \int_{L_1(t)} [c(\tau, x_0)] \, d\tau \right) < +\infty,
\]

(48)

\( \forall t \in \mathbb{R}_+ \)

leads to \( \lim_{t \to \infty} u(t) = 0 \) exponentially and the \( \lim_{t \to \infty} y(t) = 0; \forall x_0 \in \mathbb{R}^n \) since \( G(s) \) is strongly strictly positive real so that the internal state of any minimal state-space realization is uniformly bounded, and it converges asymptotically to zero as time tends to infinity. Thus, asymptotic hyperstability follows for any \( \phi : [0, t] \times \mathbb{R} \to \mathbb{R} \) satisfying (38). As a result, Property (iv) has been proven.

Note that the property of asymptotic hyperstability is independent of each particular controller provided that it belongs to a class that satisfies the integral relation (39) for some positive finite real \( \gamma \). The particular case when the nonlinear controller is nonlinear, but time-invariant, while satisfying the corresponding integral constraint (39), is said to be the Popov-type absolute stability problem involving closed-loop global asymptotic Lyapunov’s stability. If the input-output euclidean inner product (associated with instantaneous power) under the integral symbol, rather than the inner product on the Hilbert space (associated with the energy), satisfies a parallel inequality, then the problem is said to be that of the Lure’s absolute stability problem [4–8]. It is, therefore, useful to describe the global asymptotic stability of classes of closed-loop systems of the given form under certain tolerated components dispersions. Proposition II also implies directly that any nonminimal state-space realization associated with strictly stable zero-pole cancellations of the transfer function is globally asymptotically Lyapunov stable. This follows since the transfer function remains invariant under zero-pole cancellations, so it is identical to that of the minimum state space realization, so that the operator is kept strictly positive and invertible although either controllability or observability (or both) becomes lost [29–31]. A generalization of the previous result to the study of hyperstability of composite connections [32] as well to Ulman-type extended stability [33, 34] of continuous-time dynamic systems can be performed based on the study given in [32].

The subsequent example is a discrete version of the previous one.

Example 2. Example I has a direct parallel discrete-time counterpart as discussed in the sequel. Define the truncated sequence on \( [0, kT]; \forall k \in \mathbb{Z}_{0+} \) of the real sequence \( \{f_k \equiv f(kT)\}_{k \in \mathbb{Z}_{0+}} \) as follows:

\[
f_j(k) = P_j f (kT) = \begin{cases} f_j(kT) & \text{for } j \in [0, k] \cap \mathbb{Z} \\ 0 & \text{otherwise} \end{cases}
\]

(49)

\( \forall k \in \mathbb{Z}_{0+} \)

where \( T > 0 \) is the sampling period. Thus, the output of a single-input single-output linear continuous-time dynamic system of \( n \)th order and initial state \( x(0) = x_0 \in \mathbb{R}^n \) under a piecewise continuous control with eventual isolated bounded discontinuities \( u : \mathbb{R} \to \mathbb{R} \cap H \), now the Hilbert space being \( H = e^{2L}(\mathbb{Z}_{0+}) \), is

\[
y_k = \sum_{j=0}^{k} g^d(k, j) u_j + c(k, x_0) \\
= \sum_{j=\infty}^{k} g^d(k, j) u_j + c_k(x_0) \\
= (g^d \ast u)(k) + c_k(x_0), \quad \forall k \in \mathbb{Z}_{0+},
\]

(50)

where \( \mathbb{Z}_{0+} = \{ z \in \mathbb{Z} : z \geq 0 \} \), "\( \ast \)" stands for the discrete convolution operator, \( c_k = c_k(x_0) \equiv c_k(kT, x_0) \) and \( (g^d(k, j))_{k,j \in \mathbb{Z}_{0+}} \) is the impulse response sequence since the dynamic system is realizable \( g^d(k, j) = 0 \) for \( j > k \). If this dynamic system is the same system as in the previous example subject to a piecewise control sequence \( \{u_k\}_{k \in \mathbb{Z}_{0+}} \), with \( u_k = u(kT); \forall k \in \mathbb{Z}_{0+} \), then \( g^d(k, 0) = (1 - q^{-1})L^{-1}(G(s)/s)_{k=0} \); \( \forall k \in \mathbb{Z}_{0+} \) where \( q^{-1} \) is the one-step delay operator such that \( f_k = q^{-1} f_{k+1} \). In this case, the discrete controller is

\[
u_k = k r_k - \phi_k(k, y_k); \quad \forall k \in \mathbb{Z}_{0+}.
\]

(51)
Proposition 12. Assume that

1. \( k, r \in \ell_{\infty}(\mathbb{Z}_{0+}) \) so that \( \sup_{j \in \mathbb{Z}_{0+}} |k_j| \leq \bar{k} < \infty \) and \( \sup_{k \in \mathbb{Z}_{0+}} |r_k| \leq \bar{r} < \infty \),

2. the discrete function \( G^d(z) \) is strongly strictly positive real; that is, \( \text{Re} \ G(z) > 0 \) for all complex \( z \) with \( |z| \geq 1 \).

3. \( +\infty > \lim_{k \to \infty} \sup_{k \in \mathbb{Z}_{0+}} |y_k(x_0)| \geq \lim_{k \to \infty} \inf_{k \in \mathbb{Z}_{0+}} |y_k(x_0)| > 0 \), \( \forall x_0 \in \mathbb{R}^n \).

Then, one gets the following properties for any given initial state \( x_0 \in \mathbb{R}^n \).

(i) \( u, y \in \ell_{\infty}(\mathbb{Z}_{0+}) \).

(ii) \( \lim_{k \to \infty} \inf_{j \in \mathbb{Z}_{0+}} (\sum_{j=0}^{\infty} y_j k_r(r_j) > -\infty; \lim_{j \to \infty} \inf_{j \in \mathbb{Z}_{0+}} (u_j^2 - y_j^2) r_j) \leq 0 \).

(iii) \( \text{If} \ u_j^2 \geq y_j k_r(r_j) \forall j \in \mathbb{Z}_{0+}, \text{then} \ \lim_{k \to \infty} \inf_{j \in \mathbb{Z}_{0+}} (u_j^2 - y_j k_r(r_j) = 0 \text{. If, in addition, } k_j = k \text{ and } r_j = r \text{ are nonzero constants; } j \in \mathbb{Z}_{0+}, \text{then} \ \lim_{j \to \infty} \inf_{j \in \mathbb{Z}_{0+}} y_j = y_{\infty} \text{ and} \ \lim_{j \to \infty} \inf_{j \in \mathbb{Z}_{0+}} y_j = y_{\infty} = kr(\sum_{j=0}^{\infty} g_j)^2 \).

(iv) \( \text{If } r = 0, \text{then } u_j \to 0 \text{ and } y_j \to 0 \text{ as } j \to \infty, \text{and they are both square-summable on } \mathbb{Z}_{0+}; \forall x_0 \in \mathbb{R}^n \).

Thus, the closed-loop discrete dynamic system (50)-(51) is asymptotically hyperstable for any controller device of output sequence \( \varphi_k = \varphi_k(k, y_k) \) \( k \in \mathbb{Z}_{0+} \) satisfying the discrete summation inequality \( \sum_{j=0}^{k} \varphi_j(j, y_j) y_j \geq -y_k(x_0) \); \( \forall k \in \mathbb{Z}_{0+} \).

The following example links asymptotic hyperstability of a discrete dynamic system with a unique equilibrium point which is also a fixed point.

Example 3. Assume that, in Example 2, a feedback stabilizing discrete control law \( u_t = -\varphi_1(t, y_{t-1}) y_{t-1} \) satisfying the constraint \( \sum_{j=0}^{\infty} \varphi_1(j, y_j) y_j \geq -y(x_0) \geq -y > \infty; \forall j, t \in \mathbb{Z}_{0+} \) is injected to the system (1), neglecting initial conditions, and equivalently if the initial conditions are zero (this assumption does not affect the stability study,) we get

\[
P_t y = y_t = -(P_t G u_t = -(P_t G \varphi_t(t, y_{t-1}, P_{t-1})) y_t = -(P_t G \varphi_t(t, y_{t-1}, P_{t-1})) y_t \forall t \in \mathbb{Z}_{0+}.
\]

so that the closed-loop system can be described by the operator \( Q : H_{\mathbb{C}} \mathbb{C}^2(\mathbb{Z}_{0+}) \to H_{\mathbb{C}} \mathbb{C}^2(\mathbb{Z}_{0+}) \) represented as

\[
y_t = P_t Q P_{t-1} y = -P_t G \varphi_t (t, y_{t-1}, P_{t-1}) y; \forall t \in \mathbb{Z}_{0+}
\]
or, equivalently, as

\[
P_t (I + G \varphi_t(t, y_{t-1}, P_{t-1}) y_{t-1}) y = 0; \forall t \in \mathbb{Z}_{0+}.
\]

Assume that \( Q : \mathbb{C}^2[0, z) \to \mathbb{C}^2[0, z) \) for any \( z \in \mathbb{Z}_+ \) is stable, positive, one-to-one, and of closed range. Then, \( Q : H_{\mathbb{C}} \mathbb{C}^2(\mathbb{Z}_{0+}) \to H_{\mathbb{C}} \mathbb{C}^2(\mathbb{Z}_{0+}) \), where \( H_{\mathbb{C}} = \bigcup_{z \in \mathbb{Z}_+} \mathbb{C}^2[0, z) \)
is positive, bounded and of closed range, invertible and of non-zero minimum modulus; and
\[ 0 \leq E(t) = \langle P_{Q(\mathbf{t})}y, P_{y}y \rangle \leq \gamma < \infty \quad \forall t \in \mathbb{Z}_{0^+}. \]  
\[ (58) \]
Since \( E(t) \) is nonnegative, bounded, and nondecreasing, \( y_{t} \to 0 \) as \( t \in \mathbb{Z}_{0^+} \to \infty \), and then \( u_{t} = -q(t, y_{t-1})y_{t-1} \rightarrow 0 \) as \( t \in \mathbb{Z}_{0^+} \to \infty \). One gets for any given finite integer \( T > 0 \) that
\[ \lim_{T \to \infty} (P_{e_{T}}u_{t} - P_{y}y) = \lim_{T \to \infty} (P_{e_{T}}y_{y} - P_{y}y) = 0. \]
Thus, \( \mathcal{F}(\mathbf{t}) = \mathcal{F}(\mathbf{t}^2)[t, t + T] \to H_{y}y[2 \times 2 \times 2 \times 2; t + 2T] \forall t \in \Gamma. \)
